

# When One Has Lemons ...

---

Martin Casado *(Stanford)*  
Tal Garfinkel *(Stanford)*  
Weidong Cui *(Berkeley)*  
Vern Paxson *(ICSI)*  
Stefan Savage *(UCSD)*

# What this Talk is About ..

---

**Spurious Traffic**

(generally unwanted traffic on the Internet)

+

**Opportunistic (*parasitic*) Measurement**

(exploiting existing traffic for unrelated measurement)

=

**Useful Internet Measurement(?)**

# Limits Traditional Measurement

---

- ◆ Much of Internet is “hidden” from view
  - ◆ NAT
  - ◆ Proxies
  - ◆ Firewalls
- ◆ Relatively Few Sources  
(planetlab has 620)
- ◆ Limited diversity  
(typically, academic networks, near the core)
- ◆ Limited to socially acceptable traffic patterns
- ◆ Privacy issues with passive measurement

# However ...

## Lots of “Unwanted” Traffic on the Internet

---

- ◆ Malware, misconfigurations, ...
- ◆ Many Sources
  - ◆ 359,000 for Crv2
  - ◆ 16,000 large automated scan
- ◆ Great Diversity
  - ◆ 159 countries from 38,000 spam sources
  - ◆ often from poorly administered machines
  - ◆ residential bias
- ◆ Extreme Traffic Patterns
  - ◆ Internet scale network events
  - ◆ antisocial

# Opportunistic Measurement

---

- ◆ Use **existing** traffic for **unrelated** measurement purposes
- ◆ Collect using network telescopes
- ◆ Infer network properties
  - ◆ About the sender
  - ◆ About the Internet
  - ◆ About the collection site
  - ◆ ...

# Talk Outline

---

- ◆ Spurious Traffic Classes
- ◆ Example Opportunistic Measurement Studies
- ◆ Getting the most from your lemons
- ◆ Limitations
- ◆ Conclusions

# Spurious Traffic ...

---

- ◆ Generally “unwanted”
- ◆ Worms
- ◆ Spam
- ◆ Automated scans
- ◆ Misconfigurations
- ◆ Static settings, defaults
- ◆ ...

# Useful Traffic Generators

---

- ◆ Worms
  - ◆ Large number of sources
  - ◆ Code is readily available
  - ◆ Known scanning patterns
  - ◆ Initial outbreaks create “stress” conditions
- ◆ Automated Scans
  - ◆ large number of sources
  - ◆ can generate large, predictable bursts
  - ◆ often generate more traffic than worms  
(want to find more information)

# Example Event Eurasian Scan

---

- ◆ From China, Japan, Germany and Korea
- ◆ Have identified 16,000 unique hosts
- ◆ Visible each day at Stanford, CAIDA, LBNL
- ◆ Regular, within 5 minutes
- ◆ **LOUD** and intrusive
- ◆ SYN packets to 9898(Dabber), 1023(Sasser), 5554(Sasser)

# Useful Traffic Generators

---

- ◆ Spam
  - ◆ Source of “significant” TCP flows
  - ◆ Many sources
  - ◆ Often sent from compromised end-hosts  
(doesn't require scanning worm to have infected)
  - ◆ Flows can be “directed” to different collection locations
- ◆ Network (Mis)Configurations
  - ◆ NetGear static NTP configuration
  - ◆ Preconfigured source address for DDoS tool

# Example

## NAT Study Using Code Red II

---

- ◆ How many sources behind NAT?
- ◆ Released in 2001
- ◆ Infects vulnerable IIS servers
- ◆ Still active source of traffic
- ◆ HTTP connection scans
- ◆ Preferential scanning
  - ◆  $\frac{1}{2}$  of scans to local /8
  - ◆  $\frac{3}{8}$  of scans to local /16
  - ◆  $\frac{1}{8}$  of scans to full Internet

# Code Red II

expect roughly  $2^{10}$  more packets here

6 / 24s in 192/8

4 / 16s not shared w/ private (used as baseline)

one / 16 shared with 169 / 8

192/8

192.168/16

192.168.1.23

Internet

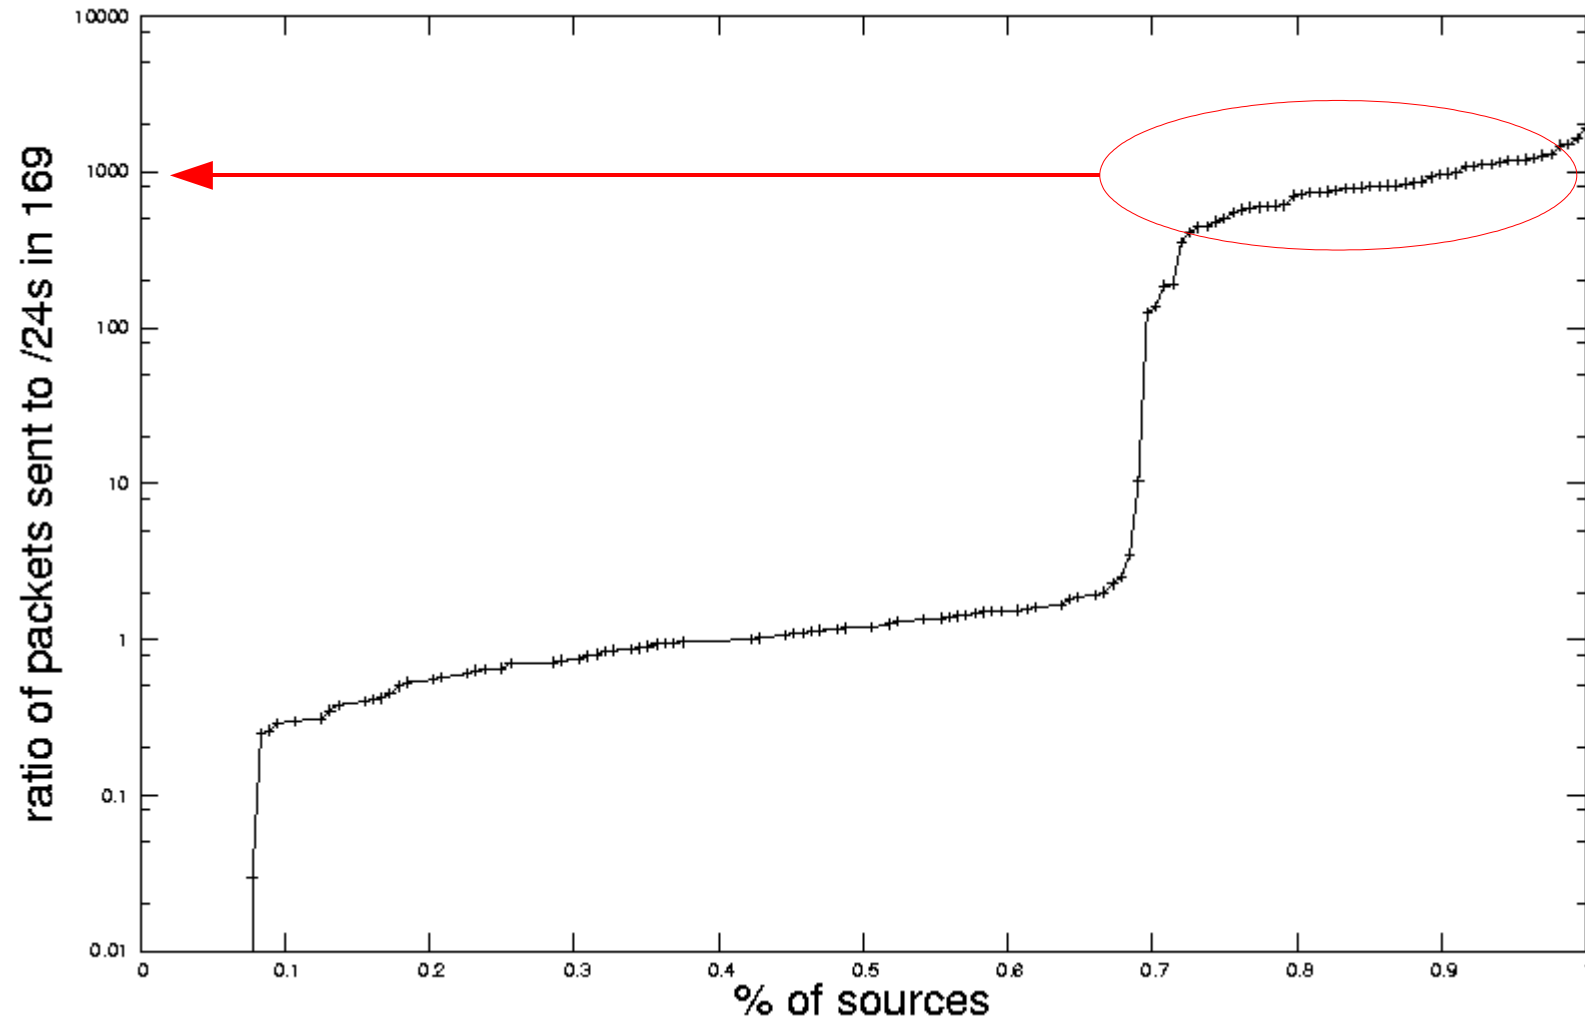

Used traces from 48-hour period  
487,291 scans from 1,528 sources

# Ratio of Packets Sent to 192

# Ratio of Packets Sent to 169

# Comments on Results

---

- ◆ 65% of machines appear to be behind NAT ..  
**however**
- ◆ NAT reduces chance of infection
- ◆ IIS less likely to be behind NAT
- ◆ Other private prefixes (e.g. 10/8 and 172.16)
- ◆ CRII is old ... biased demographic

# Example

## A Heavily Spammed Domain

---

- ◆ Long online life
- ◆ Up to 1 million emails daily
- ◆ Over 40,000 source addresses
- ◆ Can produce “significant” tcp flows
  - ◆ MultiQ tool from M&M tool suit (*Katti, et. al 2004*)
  - ◆ 24,698 “significant” flows
  - ◆ 2,269 sources
  - ◆ 70% at cable speeds or below
  - ◆ 15-20% at OC12 speeds

# Bottleneck Link Bandwidth From Spam Sources

# Getting the Most Juice out of your Lemons

---

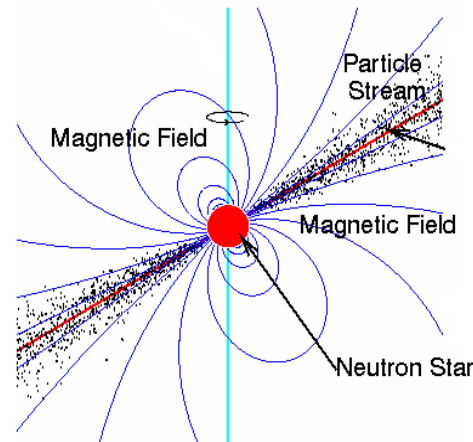

# General Classification

---

- ◆ Pulsars

- ◆ Reliably send traffic over period of time
- ◆ Endemic worms
- ◆ Identified scans

- ◆ Super Novas

- ◆ Flash events
- ◆ Worm outbreaks
- ◆ DDoS attacks
- ◆ Large scans

# Other Properties

---

- ◆ Queuing delay via packet-pair variance
- ◆ Bottleneck link bandwidth
- ◆ Drop/filtering rates
- ◆ TTL studies (“depth of the Internet”)
- ◆ *Super Nova* can reveal capacity limits
- ◆ End host characteristics (e.g Witty Worm *Kumar et al, 2005*)
  - ◆ Number of disks
  - ◆ Link speeds
  - ◆ Uptimes
  - ◆ Infection tree
  - ◆ Patient zero
  - ◆ Target was military base

# Calibrating Collection Sites

---

- ◆ Use *pulsars* with known distributions
- ◆ ... or use movable target
- ◆ Determine telescope biases
  - ◆ filtering rules
  - ◆ drop rates
  - ◆ rate limits

# Growing Lemons: Attractors and Agitators

---

- ◆ Natural Attractors (hot spots)
  - ◆ Attract some or all of the traffic from a source
  - ◆ Examples
    - ◆ default configurations
    - ◆ scanning biases based on local configuration
- ◆ Agitators
  - ◆ Cause a source to send more traffic (e.g. honeynet responder)
- ◆ Chumming
  - ◆ Steps to draw attackers (e.g. Irc server)

# Summary

---

- ◆ Traditional measurement is limited by
  - ◆ Sources
  - ◆ “Opacity” of the edge
  - ◆ Ability to send disruptive traffic
- ◆ Spurious traffic has complimentary properties
  - ◆ Many sources
  - ◆ Great diversity
  - ◆ Extreme traffic conditions

# However ...

---

- ◆ Noisy
- ◆ Lack of knowledge/control of sending environment
- ◆ Generally biased source sets
- ◆ Limited by available traffic

# Yet ...

---

- ◆ Preliminary studies provide promising results
- ◆ Can aid traditional measurement studies
- ◆ Much work remains to be done to develop and refine techniques

# Questions?

---
